

1 Feature: Return auditable validation results through an API
2
3 As an API consumer
4 I want machine-readable and reviewer-readable validation results
5 So that findings can be corrected, explained, stored, and audited
6
7 Background:
8 Given a UAD 3.6 appraisal report package has been validated
9
10 Scenario: Return a structured validation response
11 When validation is complete
12 Then the API response includes a validation run identifier
13 And the API response includes the UAD version
14 And the API response includes the rule set versions applied
15 And the API response includes a summary count by severity
16 And the API response includes all findings
17
18 Scenario: Return auditable finding details
19 Given a validation finding exists
20 When the finding is returned
21 Then the finding includes a finding identifier
22 And the finding includes severity
23 And the finding includes the affected XML location
24 And the finding includes the affected graph resource IRI
25 And the finding includes the governing rule identifier
26 And the finding includes the source specification reference
27 And the finding includes the observed value when applicable
28 And the finding includes the expected condition when applicable
29
30 Scenario: Explain a finding
31 Given a validation finding exists
32 When the client requests an explanation for the finding
33 Then the service returns a plain-language explanation
34 And the explanation cites the governing rule or specification source
35 And the explanation does not replace the authoritative validation result
36
37 Scenario: Review freeform revision history detail
38 Given a UAD 3.6 appraisal report package contains Revision History Detail text
39 When the client requests freeform revision-history review
40 Then the service evaluates the text for likely responsiveness to reported findings
41 And the service returns reviewer-assistance comments
42 And the service marks the comments as advisory
43 And the service does not treat advisory comments as deterministic validation failures
44
45 Scenario: Query rules through the API
46 When the client requests the available UAD 3.6 rules
47 Then the service returns rule identifiers
48 And each rule identifies its source
49 And each rule identifies whether it applies to Fannie Mae, Freddie Mac, or both
50 And each rule identifies its current version status
51
